

Information in Unsupervised Learning

Friday, 8 November 2019 14:20 (20 minutes)

Information bottleneck theory explains that neural networks maximally compress unnecessary information in input data, and transfer sufficient information to output. Unlike the supervised learning, the information flow of unsupervised learning has not been explored much. In this talk, I introduce the information extraction of unsupervised learning by using a representative generative model, deep belief networks. Then, I show that the unsupervised learning maximally extracts relevant information given a fixed information compression for its internal representations. This relation between the information bottleneck theory and our theory reminds the duality between the rate distortion theory and channel capacity in information theory.

[00] Information bottleneck theory explains that neural networks maximally compress unnecessary information in input data, and transfer sufficient information to output. Unlike the supervised learning, the information flow of unsupervised learning has not been explored much. In this talk, I introduce the information extraction of unsupervised learning by using a representative generative model, deep belief networks. Then, I show that the unsupervised learning maximally extracts relevant information given a fixed information compression for its internal representations. This relation between the information bottleneck theory and our theory reminds the duality between the rate distortion theory and channel capacity in information theory.

Presenter: Prof. JO, Junghyo (Seoul National University)

Session Classification: Invited talks - Physics and Astronomy 2
